

A single phenotype-bit flip spreads farther in the river than in the feedback-cut control
(same seed, same RNG tape, same construction; single-seed sweep over all 80 sites, $L=80$)

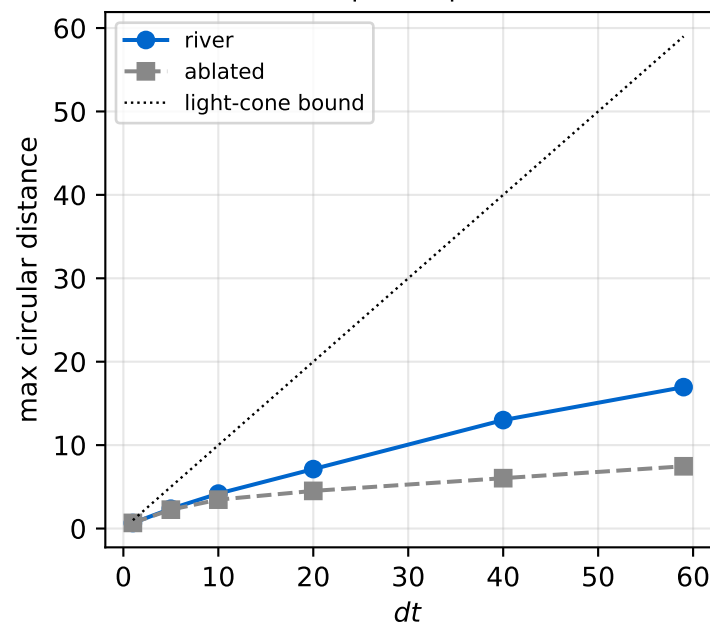

flip one phenotype bit at site 20 (damage at $dt=59$: 20 cells) flip one phenotype bit at site 40 (damage at $dt=59$: 20 cells) flip one phenotype bit at site 60 (damage at $dt=59$: 12 cells)

(a) damage mass vs matched control

(b) spatial spread

(c) 22/80 sites are dead ends
